

# How to Launch a **FinTech Project** in 100-days

The Ultimate MVP  
Delivery Guide

Time to market is a critical factor for any company aiming to launch a new digital product or upgrade the existing one. In many cases, companies do not have the expertise and proven methodologies to target aggressive product delivery timeboxes. So they search for vendors with such expertise.

Based on our experience working with 100-plus clients on [Digital Product launch and delivery](#) we came up with an approach for delivering Minimum Viable Product (MVP) in 100 days. **Therefore in this guide, we'd like to share our experience and knowledge with you and unveil all secrets of a successful product launch.** With that being said, let's get started.

## Minimum Viable Product: Required team and crucial roles

To begin with, let's define MVP. Basically, it is a **basic version of a digital product** with enough features to validate product ideas, market demand, and collect customer feedback.

Many startups have started with minimum viable product development and transformed into solid huge projects with time. So we definitely recommend it, especially if you have a complex project in mind but are not sure whether you should invest a lot of time and money in it.

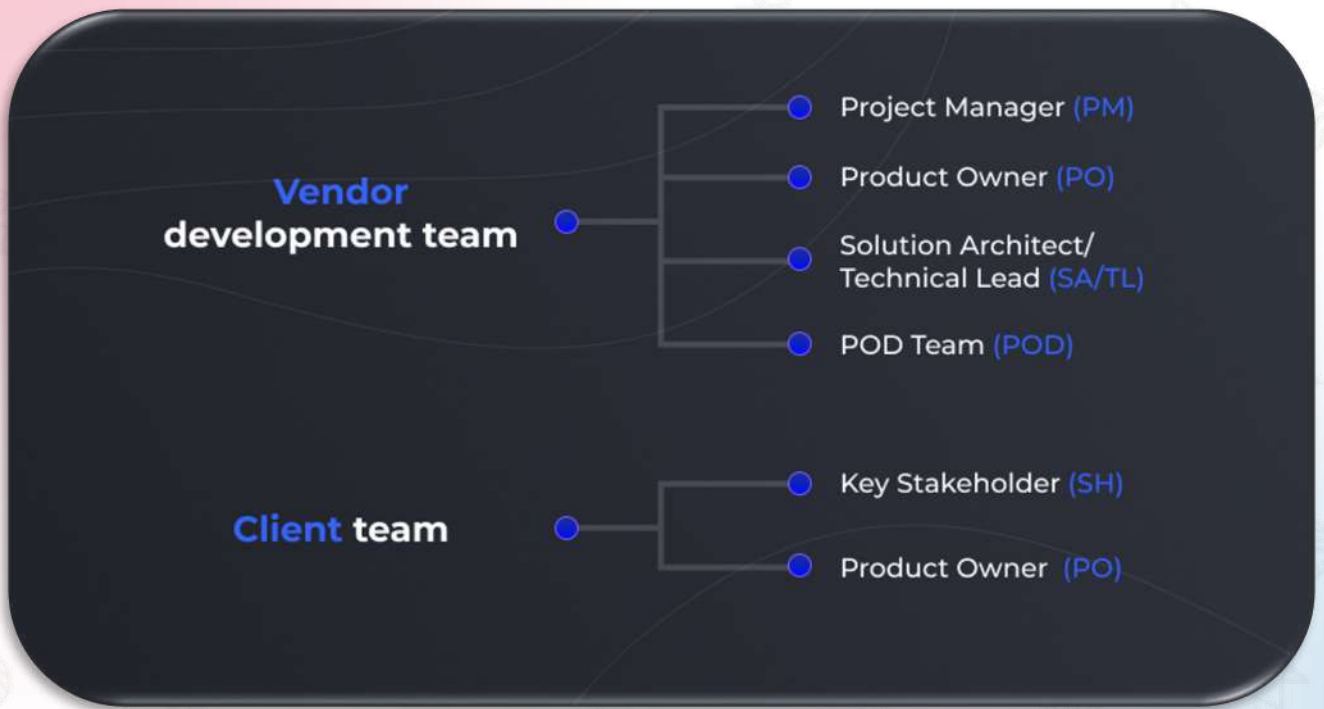

# Advantages of MVP

A minimum viable product allows FinTech companies:

- ✔ work out the main pain points prioritize features;
- ✔ test the business idea and hypotheses about the product using real data;
- ✔ identify trends that can be used in the development of the full version of the product;
- ✔ define key performance indicators for the actual product;
- ✔ reduce the risk of major financial losses in the event of a failed product release;
- ✔ reduce the cost of development by prioritizing important and identifying unclaimed functions;
- ✔ speed up error detection and internal product testing;
- ✔ find early adopters and build a user base before a full-scale launch;
- ✔ occupy a market niche and attract investors ahead of competitors.

As you can see, an MVP product launch can be a great starting point, but only if you've done everything right. That is why it is so important to hire a professional team of developers who will not only write high-quality code but also communicate with you and keep you updated about project progress up to the MVP launch.

## Vendor development team

To illustrate great development team composition, we took our own as an example. Altamira team includes the following roles:

### Project Manager (PM)

is responsible for overall product delivery, including such key things as a development process, engineering practices, quality assurance, staffing, and reporting.

### Product owner (PO)

is responsible for product vision, business idea(s) gathering, requirements management, product backlog prioritization, acceptance of done work, and continuous feedback to the engineering team.

### Architect/ tech lead (SA/TL)

is responsible for architectural solutions, technological stack proposals, technical team guidance, and coaching.

### POD team

one or several cross-functional teams, having all required roles inside to implement product features independently FE/BE developers, QA/QC engineers, DevOps engineers, etc.

# Client Team

Apart from the vendor team, there is also a client team. The fruitful cooperation between the two teams helps to save time and achieve a successful product launch. The client team usually includes two main roles:

## Key stakeholders (SH)

a decision maker on the client side responsible for the success of MVP delivery and vendor engagement.

## Product owner (PO)

optional and agreed with the client during the alignment phase.

When it comes to the development of minimum viable products for startups and businesses, they all go through several main phases. Each phase is well organized and helps us to proceed with the launch strategy while preserving all deadlines and set time frames. Vendor and client teams both participate and make certain input to the project. Let's take a look at all development phases and what they include right away.

# #1 Alignment phase

At this phase, the vendor team is working with the client team on onboarding to propose an approach for 100 day MVP delivery framework and receiving a buy-in. This is one of the most important elements that can't be taken lightly.

While starting the Discovery phase we aim to receive formal and informal buy-in from the client team, and confirmation of the understanding of all the roles, inputs, and artifacts needed for the successful execution of the next stages of digital product creation.

# #2 Discovery phase

The goal of this phase is to complete market research, validate business ideas, and test how the product fits customer needs and how we can build it. The vendor team prepares everything for active development including business domain understanding, architectural vision, technological stack proposal, MVP scope discovery, minimum feature set, appropriate POD Teams setup, development process, launch strategy, etc.

# Customer perspective

These activities require the collaboration of our team with client stakeholders and should provide the answers to the following questions:

- 👉 Do we understand product opportunities?
- 👉 Do we understand the user or target market?
- 👉 Do we understand the user's problems?
- 👉 Have we identified possible solutions?
- 👉 Have we validated the proposed solutions?

Among the artifacts that can be produced at this stage, there are Lean Canvas, Customer Persona, etc.

## Customer persona

### Samantha Taylor

31 years old  
Cafe Owner

Samantha is the owner of a small cafe downtown. She is a woman of determination, optimism, and kindness. Samantha keeps an eye on how her waiters and cooks work. She knows that the staff is the face of the entire cafe. Therefore, every employee should always look tidy and neat. Hence, why Samantha uses laundry services once or twice a week. So, she selected one laundry based on her friends' recommendations.

#### Wants & Needs

1. The employees' uniforms should be cleaned and ironed.
2. The carpets and sofa covers from my cafe require cleaning.
3. I need to know the exact time when my order will be completed.
4. I want neither to fulfil this routine nor hire someone to do it.
5. I want to save time.

#### Pain Points

1. I can't get in touch with a support representative or at least a chat bot any time I want to as there is no 24/7 support feature/capability.
2. The order tracking works incorrectly.
3. The quality of the washing machines is low, so some branded elements or even online uniforms get ruined.
4. The service price is unjustifiably high.

### John Davids

45 years old  
Sales Manager

John is an exemplary family man with a wife and three kids. Both parents work hard and try to split housework equally for fairness sake. John and his wife value their time and want to spend it with their kids. John always feels as though he is "stretched thin" because he has to take care of the kids and work. In addition, there is not enough money to cover all of the expenses. He often uses laundry services; however, the laundromat is located quite far away from his house. When John visits that laundromat once a week, he shops during his laundry's wash cycles.

#### Wants & Needs

1. To wash all of the family's clothing in one go while also not ruining them as resources are scarce.
2. To make his wife's life easier by freeing up some of her time.
3. To save on municipal services while paying less for electricity.
4. To receive hypoallergenic and baby detergents.

#### Pain Points

1. I lose time on the way to the laundromat and on my way back home.
2. Some clothing items get lost in the laundromat, and I cannot prove it or do anything about it.
3. My laundry is delivered in a plain bag.
4. The quality of service is not worth its price.

## Engineering perspective

There are several activities/artifacts that have to be prepared from an engineering perspective to start active digital product development. Some of them assume POD Team engagement, so staffing has to be performed as a preliminary step. Both vendor and client teams participate in the process.

## Product/business perspective

The list of the activities/artifacts mentioned below has to be prepared from a product/business perspective and some of them assume PO engagement, so it is critical to be aligned between the PO and product team as a preliminary step.

### Complimentary consultation

## #3 Development phase

For the active development phase short cycle iterative processes (one-week or two-week Scrum or XP) or more flow-oriented Kanban (for more mature teams) could be used. A short delivery cycle is important for continuous feedback from the business side and according to goals/roadmap adjustments.

The development phase has releases, like Beta one, to validate some assumptions and decisions. Problem–solution, architecture, technological stack, etc. can be validated and some corrections implemented when required.

And now we would like to define some key elements of the development phase that you should keep in mind while working on your digital product.

## Quality

Well-established QA processes must be focused on embedding quality in the product instead of controlling it and fixing continuously. Improper QA processes are one of the largest waste generators in the development cycle.

Each product/project is unique and has its own quality requirements. Most aspects of quality control have to be implemented as quality gates and Definition of Done at different levels (development task, story, iteration, product release).

## Unsure about your **product quality**?

Request an audit from your current vendor or your in-house development team.

## Engineering practices

The set of engineering practices depends on team maturing and product/technological context, but general recommendations must be taken into account. They are the following:

- 👉 code standards have to be defined by POD and shared in the common Knowledge Base;
- 👉 dedicated quality gates in specialized tools like SonarQube have to be configured for defined code standards to control them during further development;
- 👉 shift code standards left with common IDE settings and additional plugins to detect and prevent violations on the developer's machine;
- 👉 code review practice has to be established with a proper leadership model and tooling;
- 👉 test automation has to be implemented, measured, and controlled according to the approved QA strategy;

- 👉 all CI/CD pipelines have to be configured including policies, rules, and environments;
- 👉 containerization approach is preferable for artifacts delivery because CI/CD, configuration management, and environments preparation could be done in a common way and differences between environments are significantly reduced;
- 👉 accelerators could be used to speed up initial technical setup (VCS, code review, CI/CD, SonarQube) and make it more standardized.

## Reporting

It is very important to make the development process completely transparent and with key metrics gathering and trends monitoring. Traditional tools like JIRA, CI/CD, and SonarQube reporting dashboards have to be configured to see not only the current picture from all perspectives but historical trends:

- 👉 product roadmap and release burndown with optimistic/pessimistic predictions;
- 👉 current iteration or development state on the task board;
- 👉 quality metrics like defects count, defects distribution by components, and severity;
- 👉 quality control metrics like test coverage, manual and automated test execution statistics, tests distribution by level;
- 👉 maintainability metrics like code standards violations, potential defects, and security issues.

## Pro tip

Reporting is the main KPI that every engineering product team must track.

[Request a checklist!](#)

## Scope and requirements management

The main idea of scope management is to make it very value-driven with a focus on MVP product delivery.

Instead of fixing product scope, it is important to reflect on initial feedback gathered from all involved parties. Continuous scope reprioritization by value helps leave only the most important parts to meet deadlines and maximize achieved business value.

The starting point for discussing the product requirements has to be the Product Vision. The document describes the critical functionality of the product, value proposition, target audience, business, and user needs. It is used to create alignment and a shared understanding of the product for everyone involved in the development effort including stakeholders and the development team.

All ideas have to be prioritized by business value and could be estimated in complexity points by POD to get some understanding of feature cost.

## Requirements preparation pipeline

It is critical to implement only well-defined ready for development requirements to avoid waste. But it is not always the case because PO is not always disciplined enough, and some uncertainty/unknowns are present in most ideas.

Visualization of all stages of requirements preparation helps to reduce waste and improve requirements quality. Each stage has a clear Definition of Ready and WIP (work in progress) limit to avoid multitasking. Having such a pipeline in hand, it is easy to identify bottlenecks in the requirements preparation process and manage risks.

## Final thoughts

When using proven approaches based on 10-plus years of experience developing digital products for different business industries, it becomes possible to make client-vendor relations work very efficiently.

In this guide, we demonstrated an approach that significantly reduces risks, and wastes and increases the predictability for the client. With it, we can achieve a minimum viable product developed within a 100 days fixed timebox. So if you need a reliable team to build your MVP fast without compromising project quality, just drop us a line and we will help you with everything.
